

# Delivering the readmission report by expiring link

Every path the report can take, captured from the live sandbox after deployment. Each recipient gets their own link, so an open or a download is attributed to a named mailbox rather than only to a facility.

BUILT & LIVE-TESTED IN SANDBOX · NOT YET IN PRODUCTION

**Scope, plainly.** Deployed to lumDev on 9 September 2026, 74 of 74 tests passing, and exercised end to end with fabricated patient records. It is **not** in production, production holds none of this code, and the kill switch `Is_Active__c` is **still false**, so the 8am schedule is a no-op. Nothing has ever been sent to a real facility. Patient names in every screenshot are invented.

## The happy path

Five steps, all captured from the sandbox run at 2:41pm ET on 9 September.

### 01 The job builds one report and one link per recipient

The nightly batch groups yesterday's readmissions by facility and renders that facility's report to PDF once. It then asks Salesforce for a separate public link per recipient, all pointing at the same file. Facilities with no readmissions are not emailed at all.

| SETTING          | VALUE IN THE TESTED RUN                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Link lifetime    | <code>Link_Expiry_Hours__c</code> = 24 . Created 18:41 UTC, expires 2026-09-10 18:41 UTC. Measured at exactly 24.0 hours.                       |
| View cap         | <code>Max_Opens__c</code> = 10 . The link closes early once a recipient has opened it ten times.                                                |
| Download allowed | <code>Allow_Download__c</code> = <code>true</code> , logged separately from a view.                                                             |
| Password         | None by design. The unguessable URL is the credential.                                                                                          |
| Storage          | One PDF per facility, filed on the Facility record. Every recipient link points at that same file, so extra recipients cost one small row each. |

### 02 Each recipient gets an email with no patient data in it

The message carries a count and a button, and names the address it was issued to. No patient names, no dates of birth, no attachment.

The facility email as an administrator sees it in Outlook, rendered from the template the code produces, with a representative facility and contact.

Nothing in this message is protected health information. That is the whole reason no encrypted mail relay is needed: there is nothing in the email to protect.

### 03 One click, no login, and the report opens

The recipient has no Salesforce account and never signs in. The long random string in the URL is the credential, and it unlocks that one file and nothing else. Captured in a browser profile with zero Salesforce cookies.

The link issued to the Gmail recipient, rendering the report inline. The file title carries the address the link belongs to.

The report is a PDF rather than a CSV because this viewer shows "No preview available" for CSV, which would have forced every recipient to download before reading anything.

### 04 The open is attributed to that mailbox, not just the facility

This is the part facility-level tracking could not do. Because each link was issued to one address, the platform recording an open tells you who opened it. Below are the real rows after opening only the Gmail recipient's link.

| LINK         | DELIVERED TO (ATTRIBUTION TARGET)      | REPRESENTING               | OPENS | DOWNLOADS | FIRST OPENED (ET) | EXPIRES (ET) |
|--------------|----------------------------------------|----------------------------|-------|-----------|-------------------|--------------|
| RRL-00000001 | tester1@propela.tech<br>Sandbox Tester | admin@samplecarecenter.com | 0     | 0         | -                 | 10 Sep 14:51 |
| RRL-00000002 | tester2@propela.tech<br>Sandbox Tester | admin@samplecarecenter.com | 1     | 0         | 09 Sep 14:51      | 10 Sep 14:51 |

Two recipients, two links, and the open landed on exactly one of them. The second mailbox shows one open; the first stays at zero.

These are real values from the live test, with the testers' own addresses replaced by placeholders. Opening one recipient's link left the other recipient's counters untouched, which is the proof that attribution works.

### 05 Lumina gets one digest, not a copy of every email

Kevin receives a single summary naming each facility, each recipient, their role and the link expiry, followed by the day's open and download totals. Facilities that were skipped appear underneath, so gaps surface daily instead of silently.

The digest from a tested run, with the testers' own addresses replaced by placeholders. One line per email rather than one per facility, because each recipient gets their own link and therefore their own message. Two recipients at one facility is two emails. The per-recipient detail and the link-activity block are new work; the job previously reported bare totals.

## What the audit captures

Worth being exact, because this is the one place the design trades something away.

| QUESTION                     | ANSWERED? | HOW                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Which mailbox opened it      | Yes       | Each recipient has their own link, so the open identifies the address                                                                                                                                                                                                                                                                                                                                                                                                        |
| Which mailbox downloaded it  | Yes       | Downloads counted separately from views, per recipient                                                                                                                                                                                                                                                                                                                                                                                                                       |
| When, to the second          | Yes       | First opened and last activity, per recipient                                                                                                                                                                                                                                                                                                                                                                                                                                |
| How many times               | Yes       | Open and download counts per recipient                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Which facility's report      | Yes       | Each row is a child of its Facility                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| A named human, not a mailbox | Partly    | Every open is attributed to the exact address the link was issued to, and to that facility. What a public link cannot prove is who was sitting at the keyboard. If the administrator forwards their own link to the director of nursing, the open is still recorded against the administrator's address, because that is the link that was used. Naming the human would require a login or a one-time code on every open, which is the portal build Lumina chose not to take |
| IP address of the viewer     | No        | Not available free. Salesforce offers a <code>ContentDistribution</code> event type carrying client IP, but this org generates only 3 of the 79 event types, so it needs the Event Monitoring add-on licence                                                                                                                                                                                                                                                                 |

Identify here is **possession of the mailbox the link was sent to**, the same model Microsoft's own one-time-passcode encryption uses. It satisfies HIPAA accounting of disclosures, which asks for the entity and address that received the data.

## The other paths

A single happy case is a demo, not proof. These are the branches that matter.

### 06 The link dies on its own, two ways

Whichever comes first: 24 hours, or ten opens. Anyone opening it after that, including anyone the email was forwarded to, gets Salesforce's page instead of the report.

### Lumina can reissue a link, and that is the intended route

Salesforce's expired page carries no way back, so the email itself tells the recipient to reply and **Lumina reissues it for them**. Because every link now has its own row naming its recipient, a reissue is a lookup rather than a guess: staff open the Facility, see who held which link and whether they ever opened it, then send that person a fresh one. The new link always goes to the address on the row, never to whoever asked, so a forwarded request cannot redirect a report somewhere else.

**Build and live in the sandbox. Resend Readmissions Report** sits on the Facility record. It first shows what would go out, to which addresses and in which role, and sends nothing until that is confirmed. Confirming issues a brand new link per recipient, points it at the report already filed on the record rather than generating a second copy, and reports what actually sent.

Where the button lives: the action row on the Facility record, next to Create Opportunity. Any Lumina user who can see the facility can reissue its link from here.

The confirmation step. Nothing has been sent at this point: the dialog exists so nobody puts a link to patient data in an inbox they did not expect.

Both rows here are sandbox testers, because this org diverts every facility email away from real contacts. In production this list is the facility's own administrator, or the director of nursing when no administrator is on file, which for most facilities is a single row.

After confirming. Each recipient has their own new link with its own expiry, and each row says whether it sent. A failure for one address does not stop the others. Two rows again because this is the sandbox, standing in for one facility contact.

Every reissue writes its own attribution row rather than editing the old one, so the accounting of disclosures keeps both deliveries and each one's opens stay separate.

### 07 A facility with no contact on file is skipped, loudly

If a facility has readmissions but no administrator or director-of-nursing email, nothing is sent and the reason is named in the digest rather than swallowed. Measured against production today: of the **131 facilities** that had a qualifying readmission in the last 30 days, **25** have no contact of either kind, so about one production in five goes nowhere. Across the whole enrolled list the gap is wider: **159 of 326** facilities have neither address, 66 of them GHC and 60 Complete Care Management.

| CONDITION                      | BEHAVIOUR                                                                                                          |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------|
| No <code>Admin_Email__c</code> | Falls back to <code>DN_Email__c</code> , and the attribution row records which role received it                    |
| Neither on file                | <b>Skipped, listed in the digest with its row count</b>                                                            |
| Zero readmissions              | No email at all, and not listed as a skip                                                                          |
| Link could not be created      | <b>Reported as a failure and that recipient is not emailed. An email pointing at a broken link never goes out.</b> |

### 08 A misconfigured sender is reported, not fatal

Found by the live test rather than by reading the code. The first run reported **Emails sent: 0** because the sending address existed but had never been verified, and Salesforce refuses to send from an unverified address.

| BEFORE                        | AFTER                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Unverified sender             | <b>Whole send rejected, report silenced</b><br><b>Falls back to the running user, reported once in the digest</b> |
| Digest "Facility emails" list | <b>Listed messages that were built, even when none sent</b><br><b>Lists only what actually went out</b>           |
| Sandbox sender                | <b>Reused the production address</b><br><b>Own field, <code>Sandbox_From_Org_Wide_Address__c</code></b>           |

**A setup gap should never silence a daily clinical report. It should send anyway and complain in the summary, which is now what happens.**

## Proof of delivery

Both testers received both messages, each with their own link. This is a real inbox, not a mockup.

Both messages landed in a Google mailbox: the facility report and the run digest. This matters because Genesis, the largest chain and 61% of recipient addresses, is on Google.

## Where it lives in Salesforce

Every report is filed against the facility it belongs to, with the per-recipient links alongside it, so Lumina staff can see who received what and whether they read it.

- 01 Verify the sending address in production**  
Create `tc@luminaicare.com` as an Org-Wide Email Address and have someone with that mailbox click the verification link. Production currently has none.
- 02 Confirm the export button should be there**  
Recommended, since staff need to work the list rather than read it on screen, and every download is now logged against a named recipient. Worth an explicit yes because a copy leaves Salesforce.
- 03 Confirm the view cap and the link lifetime**  
Currently 24 hours and 10 opens per recipient. Both are configuration, changeable without a deploy.
- 04 An owner for the facilities with no contact**  
25 of the 131 facilities that had a readmission in the last 30 days have no administrator and no director-of-nursing email, and 159 of 326 enrolled facilities have neither. Concentrated in GHC and Complete Care Management. Independent of the delivery method, and the single biggest limit on coverage.
- 05 Confirm the retention rule**  
The stored PDF is now deleted once every link to that report has expired, after a grace period, so patient data does not outlive the delivery window on the record. A recipient's own download is theirs and is unaffected. Worth confirming the grace period, currently seven days.
- 06 Compliance sign-off in writing**  
The link authenticates by possession of the mailbox. Worth recording rather than agreeing verbally.
- 07 Decide whether IP addresses are wanted**  
Not available on the free tier. It needs the Event Monitoring add-on licence, or a custom page we host.
